

Schema | Docs | HERY

The `.hery` files are YAML files with reserved properties: `_entity` , `_id` , `_body` , `_meta` . So not too complicated. That said, every entity has its own standard set of properties and data format. And those are standardized in a [JSON Schema](#) file named: `schema.hery.json` . This schema file is found in the `.<collection name>/schema.hery.json` directory.

Inside this [JSON Schema](#) file there are standards that need to be followed.

1. The naming of the schema file.

- It has the word `hery` in it for better IDE integration
- An IDE plugin can quickly identify that it is part of a HERY entity schema definition since they vary from a normal [JSON Schema](#)

2. Inside the schema file there is the `id` property

- It is required, compared to the [JSON Schema](#) standard
- It uses a HERY standard URN that is prefixed with: `urn:hery:<collection name>`:
- The URN is used so that the content of the schema can be identified as a HERY schema and so to not be confused with any other [JSON Schema](#)
- This also helps with IDE plugins
- The rest of the content is the same as `_entity` but `/` and `@` is replaced with `:`

3. The schema of an entity is always merged with `.schema/entity.schema.json` to make sure that when validation happens the standard HERY properties are also validated

HERY is for developers and developers need the technology they use to have a good integration with their IDEs. So this is why some of these standard and rules exists. It adds to the responsibility of using HERY but makes working with it with developer tools a breeze.
